a. Problems with the screen

BUG-01: No Country field
Severity: High
Description: There is no Country field, but "State or Province" is a required dropdown. The company is global, so this may stop customers outside the US from entering a correct address.
Expected: A Country field before the address. The other address fields change by the country.

BUG-02: Payment amount has no currency
Severity: High
Description: The amount shows "30.00" only. The customer doesn't know which currency it is.
Expected: Currency shown next to the amount, for example "$30.00 USD".

BUG-03: No CVV field on this screen
Severity: High
Description: The form doesn't ask for the 3 digits on the back of the card. If it's asked in the next step, this is not a bug.
Expected: A required CVV field.

BUG-04: Second address line has no label
Severity: Medium
Description: The second line under "Credit Card Billing Street Address" has no label. Users and screen readers can't tell what to enter there.
Expected: A label like "Apartment, suite (optional)".

BUG-05: Wrong title
Severity: Low
Description: The title is "Account Information", but this is a payment form.
Expected: A title like "Payment details".

BUG-06: MI field is not clear
Severity: Low
Description: The label "MI" is not explained on the form.
Expected: A clear label, like "Middle initial", or no field at all.

BUG-07: Inconsistent hint text
Severity: Low
Description: Card Number says "(No dashes or spaces)" with a capital N, Postal Code says "(no dashes)" with a small n.
Expected: Same style for all hints.

BUG-08: Old VISA logo
Severity: Low
Description: The VISA logo in the Card Type field has the gold mark on the V. This is the old logo, Visa changed it in 2014.
Expected: The current VISA logo.

Things to verify on the real page:
- The page works only over HTTPS
- The card number doesn't appear in the URL, in logs or in the browser autocomplete
- Card details go to the payment provider and are not saved on the company's server
- Error messages for wrong card number, expired card and letters in the card number
- Clicking Continue on an empty form shows an error near each required field
- After an error, the form keeps what the user already typed
- Tab order and how the form looks on a phone
- The card logo matches the selected card type
- What happens if the card type doesn't match the card number (VISA selected, Mastercard number entered)
- The page shows what the payment is for (product or plan, period, tax)

b. Test cases

Test 1 - Happy flow: successful payment
Precondition: The user is logged in and has a payment of 30.00 to make.

Step	Action	Expected result
1	Open the billing form	Form loads, amount 30.00 is shown, fields are empty
2	Select VISA	VISA is selected
3	Enter card number 4111111111111111	Number is accepted, no error
4	Select a month and year in the future	Values are selected
5	Enter first name and last name	Values are accepted
6	Enter street address, city, state and postal code	Values are accepted
7	Click Continue	The user moves to the next step according to the spec (confirmation screen or payment approved). If a charge is made, it is exactly one charge of 30.00

Test 2 - Invalid card number
Precondition: The billing form is open.

Step	Action	Expected result
1	Fill all fields with valid data	No errors
2	Change the card number to 4111111111111112	-
3	Click Continue	Form is not sent, an error is shown near the card number, other fields keep their values, no charge

Repeat with: a number that is too short, a number with letters, an expired date.

Test 3 - Multiple clicks on Continue
Precondition: The billing form is open. Slow network (DevTools throttling "Slow 3G"), so there is time to click many times.

Step	Action	Expected result
1	Fill all fields with valid data	No errors
2	Click Continue many times, fast (for example 10 times)	After the first click the button is disabled or ignores more clicks, a loading indicator is shown
3	Wait for the response	One confirmation is shown
4	Check the payment history / transaction log	Only one payment of 30.00 was made, no duplicate charges

c. Solution for the most severe bugs

1. BUG-01: No Country field (High)
Why it's first: It may stop customers outside the US from paying, and for a global company that means losing customers in whole countries.
Solution:
- Add a required Country field at the top of the address. Pre-fill it from the user's account, allow changing it.
- The address fields change by the country: State/Province only where it's relevant.
- Show the currency next to the amount and on the button (BUG-02).
- After release, compare the payment completion rate per country before and after.

2. BUG-03: No CVV field (High)
Why it's second: Without CVV it's easier to pay with stolen card details. This means fraud and chargebacks.
Solution:
- Add a required CVV field (3 digits, 4 for Amex), masked and never saved.
- Better option: use the payment provider's ready checkout or card fields (for example Stripe). It handles CVV, 3D Secure, countries and currencies, and the card details don't pass through the company's servers.
